

More About Priors I

Models for Socio-Environmental Data

Chris Che-Castaldo, Mary B. Collins, N. Thompson Hobbs

June 05, 2019

The posterior distribution uses information from both the likelihood and prior distributions. *An informative prior is more influential than an vague prior.*

Outline

- Informative priors
- Vague priors
- Conjugate priors

Informative priors

Informative priors are distributions that are not diffuse relative to the posterior. These distributions may be based on

- statistics reported in the literature
- posterior distributions from previous studies
- meta-analyses
- “plausible” assumptions

Why use informative priors?

- They speed up convergence
- They reduce problems with identifiability
- They can allow you to estimate difficult/impossible quantities

Why don't we find people using informative priors more often?

- *Cultural*: “All studies stand alone” argument
- Texts often use vague priors (including H&H)
- Hard work!
- Concerns about “excessive subjectivity”

If you wanted to use an informative prior, how would you do it?

- Strong scholarship is the basis for strong priors
- Moment match, converting means and standard deviations to usable parameters
- Pilot studies
- Allometric relationships
- Deterministic models with parameters that have specific meaning

How much does an informative prior influence the posterior?

A. Nothing new

B. Moved mean + shrinkage

C. Shrinkage

D. Increased variance (rare)

Communicating your use of informative priors

State-space modeling to support management of brucellosis in the Yellowstone bison population

N. THOMPSON HOBBS,^{1,5} CHRIS GEREMIA,² JOHN TREANOR,² RICK WALLEN,² P. J. WHITE,² MEVIN B. HOOTEN,³ AND
JACK C. RHYAN⁴

Communicating your use of informative priors

Table 3: Prior distributions for parameters in model of brucellosis in the Yellowstone bison population. Sources are given for informative priors.

Parameter	Definition	Distribution	Mean	SD	Source
β	Rate of transmission (yr ⁻¹)	uniform(0,50)	25	14.3	vague
f_n	Number of offspring recruited per seronegative (susceptible) female	beta(77,18)	.81	.04	Fuller et al., 2007
f_p	Number of offspring recruited per seropositive (recovered) female	beta(37,20)	.64	.06	Fuller et al., 2007
f_c	Number of offspring recruited per seroconverting female	beta(3.2,11)	.22	.10	Fuller et al., 2007

Communicating your use of informative priors

Vague Priors

A vague prior is a distribution with a range of uncertainty that is clearly wider than the range of reasonable values for the parameter (Gelman and Hill 2007:347).

Vague Priors

- Avoid calling a prior “uninformative” or “non-informative” rather:
 - ▶ diffuse
 - ▶ flat
 - ▶ automatic
 - ▶ nonsubjective
 - ▶ locally uniform
 - ▶ objective

Commonly used vague priors

- $\text{gamma}(.001, .001)$ for strictly non-negative quantities
- $\text{inverse gamma}(.001, .001)$ for variances
- $\text{uniform}(0, \text{some large number})$ for variances
- $\text{normal}(0, \text{a variance much greater than the mean})$ regression coefficients

Important Note: The uniform and normal must be scaled properly! For example $\beta_0 \sim \text{normal}(0, 1000)$ is extremely informative if $\beta_0 = 10000$.

Issues With Vague Priors

- Computational: failure to converge, slicer errors, failure to calculate log density, etc.
- Sensitivity: changes in parameters of “vague” priors meaningfully changes the posterior when data sets are small or when they have high variance (e.g. $\tau \sim \text{gamma}(.001, .001)$ can really be problematic, this will come up in the multilevel modeling lab)

Conjugacy

- In special cases the posterior, $[\theta|y]$, has the same distributional form as the prior, $[\theta]$.
 - ▶ For example, if you had a prior, $\text{gamma}(\alpha, \beta)$, your posterior would be $\text{gamma}(\alpha_{new}, \beta_{new})$
- In these cases, the prior and the posterior are said to be *conjugate*.

Conjugacy is important for two reasons:

- 1 Conjugacy minimizes computational work and, in more complicated cases, allows us to break down calculations into manageable chunks.
- 2 Conjugacy plays an important role in Markov chain Monte Carlo (more on this later).

Deriving the Beta-Binomial Conjugacy Relationship

We know that the beta distribution is a conjugate prior for the binomial likelihood.

- Consider calculating the posterior distribution for the parameter θ .
- θ is the probability of a success conditional on n trials and y observed successes.

Deriving the Beta-Binomial Conjugacy Relationship

Using Bayes theorem:

$$[\phi \mid y, n] \propto \underbrace{\binom{n}{y} \phi^y (1 - \phi)^{n-y}}_{\text{binomial likelihood}} \underbrace{\frac{\gamma(\alpha + \beta)}{\gamma(\alpha)\gamma(\beta)} \phi^{\alpha-1} (1 - \phi)^{\beta-1}}_{\text{beta prior}}$$

where α and β are beta prior parameters.

Deriving the Beta-Binomial Conjugacy Relationship

$$[\phi \mid y, n] \propto \binom{n}{y} \phi^y (1 - \phi)^{n-y} \frac{\gamma(\alpha + \beta)}{\gamma(\alpha)\gamma(\beta)} \phi^{\alpha-1} (1 - \phi)^{\beta-1}$$

Deriving the Beta-Binomial Conjugacy Relationship

$$[\phi \mid y, n] \propto \binom{n}{y} \phi^y (1 - \phi)^{n-y} \frac{\gamma(\alpha + \beta)}{\gamma(\alpha)\gamma(\beta)} \phi^{\alpha-1} (1 - \phi)^{\beta-1}$$

$$[\phi \mid y, n] \propto \phi^y (1 - \phi)^{n-y} \phi^{\alpha-1} (1 - \phi)^{\beta-1}$$

Deriving the Beta- Binomial Conjugacy Relationship

$$[\phi \mid y, n] \propto \binom{n}{y} \phi^y (1 - \phi)^{n-y} \frac{\gamma(\alpha + \beta)}{\gamma(\alpha)\gamma(\beta)} \phi^{\alpha-1} (1 - \phi)^{\beta-1}$$

$$[\phi \mid y, n] \propto \phi^y (1 - \phi)^{n-y} \phi^{\alpha-1} (1 - \phi)^{\beta-1}$$

$$[\phi \mid y, n] \propto \phi^{y+\alpha-1} (1 - \phi)^{\beta+n-y-1}$$

Deriving the Beta-Binomial Conjugacy Relationship

$$[\phi \mid y, n] \propto \phi^{y+\alpha-1}(1-\phi)^{\beta+n-y-1}$$

Let $\alpha_{new} = y + \alpha$ and $\beta_{new} = \beta + n - y$. Multiply by normalizing constant:

$$\frac{\gamma(\alpha_{new} + \beta_{new})}{\gamma(\alpha_{new})\gamma(\beta_{new})},$$

and the posterior of ϕ is a beta distribution:

$$[\phi \mid y, n] = \frac{\gamma(\alpha_{new} + \beta_{new})}{\gamma(\alpha_{new})\gamma(\beta_{new})} \phi^{\alpha_{new}-1}(1-\phi)^{\beta_{new}-1},$$

with parameters α_{new} and β_{new} .

Conjugate priors

Table A.3: Table of conjugate distributions

Likelihood	Prior distribution	Posterior distribution
$y_i \sim \text{binomial}(n, \phi)$	$\phi \sim \text{beta}(\alpha, \beta)$	$\phi \sim \text{beta}(\sum y_i + \alpha, n - \sum y_i + \beta)$
$y_i \sim \text{Bernoulli}(\phi)$	$\phi \sim \text{beta}(\alpha, \beta)$	$\phi \sim \text{beta}(\sum_{i=1}^n y_i + \alpha, \sum_{i=1}^n (1 - y_i) + \beta)$
$y_i \sim \text{Poisson}(\lambda)$	$\lambda \sim \text{gamma}(\alpha, \beta)$	$\lambda \sim \text{gamma}(\alpha + \sum_{i=1}^n y_i, \beta + n)$
$y_i \sim \text{normal}(\mu, \sigma^2)$ σ^2 is known.	$\mu \sim \text{normal}(\mu_0, \sigma_0^2)$	$\mu \sim \text{normal}\left(\frac{\left(\frac{\mu_0}{\sigma_0^2} + \frac{\sum_{i=1}^n y_i}{\sigma^2}\right)}{\left(\frac{1}{\sigma_0^2} + \frac{n}{\sigma^2}\right)}, \left(\frac{1}{\sigma_0^2} + \frac{n}{\sigma^2}\right)^{-1}\right)$
$y_i \sim \text{normal}(\mu, \sigma^2)$ μ is known.	$\sigma^2 \sim$ inverse gamma(α, β)	$\sigma^2 \sim$ inverse gamma($\alpha + \frac{n}{2}, \beta + \frac{\sum_{i=1}^n (y_i - \mu)^2}{2}$)
$y_i \sim \text{lognormal}(\mu, \sigma^2)$, μ is known	$\sigma^2 \sim$ inverse gamma(α, β)	$\sigma^2 \sim$ inverse gamma($n/2 + \alpha, \frac{(\log(y_i) - \mu)^2}{2} + \beta$)
$y_i \sim \text{lognormal}(\mu, \sigma^2)$ σ^2 is known	$\mu \sim \text{normal}(\mu_0, \sigma_0^2)$	$\mu \sim \text{normal}\left(\frac{\left(\frac{\mu_0}{\sigma_0^2} + \frac{\sum_{i=1}^n \log y_i}{\sigma^2}\right)}{\left(\frac{1}{\sigma_0^2} + \frac{n}{\sigma^2}\right)}, \left(\frac{1}{\sigma_0^2} + \frac{n}{\sigma^2}\right)^{-1}\right)$

Post = beta
Likelihood = binom (17, 80)
Prior = beta (1, 1)

Posterior Parameters

$$\alpha = 17 + 1 \\ = 18$$

$$\beta = 1 + 80 - 17 \\ = 64$$

$$\rightarrow \text{beta}(18, 64)$$

Why Use Conjugacy

- It is not necessary, conjugate priors will accelerate MCMC.
- For simple models, you can use conjugate priors to obtain the posterior distribution in closed form, without any simulation.

Things to remember

- There is no such thing as a uninformative prior, but certain priors influence the posterior distribution more than others.
- Informative priors, when properly justified, can be useful.
- Strong data overwhelms a prior.
- Priors represent current knowledge (or lack of), which is updated with data.
- We encourage you to think of vague priors as a provisional starting point.

Lab exercises.
